- Demonic calculus to model the behaviour of programs when the Demon is in charge of nondeterministic choices
- This can be exploited to model total correctness of nondeterministic programs algebraically [HMS20, HŠ21]

Some Definitions

$$D(S) = \{(x, x) \mid \exists y : (x, y) \in S\}$$

 $R(S) = \{(y, y) \mid \exists x : (x, y) \in S\}$

$$S; T = \{(x, z) \mid \exists y : (x, y) \in S, (y, z) \in T\}$$
$$S * T = \{(x, y) \in S; T \mid \forall z : (x, z) \in S \Rightarrow (z, z) \in D(T)\}$$

for $S, T \subseteq X \times X$

▲□▶▲圖▶▲≣▶▲≣▶ ≣ のへで

Let τ be a signature containing predicates, constants, and operations, defined for binary relations.

A τ -structure S is *proper* if there exists some base X, the elements of S are relations over X, and it is closed under the operations in τ .

The *representation class* $R(\tau)$ is the class of all proper τ structures, closed under isomorphic copies. An isomorphism mapping a τ -structure in $R(\tau)$ to a proper structure is called a *representation*.

A representation is *finite* if the image is a proper structure with its elements binary relations over a finite base *X*.

If all finite members of $R(\tau)$ have a finite representation, it is said to have the *Finite Representation Property* (FRP).

 $R(\tau)$ is said to be finitely axiomatisable if membership can be axiomatised with finitely many first order formulas.

Similarity Class with FRP

▲□▶▲□▶▲目▶▲目▶ 目 のへの

Theorem [Zar59]

 $R(\leq,;)$ is axiomatised finitely by partial order, associativity, and monotonicity. It's finite members also have the FRP.

Amend S with an identity element e to obtain S', for faithfulness.

Then let $\theta : S \to \wp(S' \times S')$ where

$$(s,t) \in a^{ heta} \Leftrightarrow t \leq s; a$$

for all $s, t \in S', a \in S$.

Theorem [HE13]

 $R(\leq, D, R, \sim, 0, 1, 1', ;)$ is axiomatised by finitely many axioms. It's finite members also have the FRP.

Define the set of good sets $\mathcal{G} \subseteq \wp(\mathcal{S})$ as the set of meet completions.

Then let $\theta : S \to \wp(G \times G)$ where

$$(S,T) \in a^{ heta} \Leftrightarrow (S; a \subseteq T \land T; \check{a} \subseteq S)$$

for all $S, T \in G, a \in S$.

- 1. Proof for FRP for ordered domain algebras [HE13] only requires ≤, *D*, *R*, ⊂, ; to be in the signature
- 2. \leq can be defined implicitly as $a \leq b$ if and only if for every representation θ we have $a^{\theta} \leq b^{\theta}$
- 3. Range can be defined implicitly $R(a) = D(\check{a})$

Proposition

FRP holds for the similarity class

$$\{D, \smile,;\} \subseteq \tau \subseteq \{\leq, \smile, D, R, 0, 1, 1',;\}$$

R(D, R, *) is not Finitely Axiomatisable

◆□▶ ◆□▶ ◆三▶ ◆三▶ ・三 ・ つへぐ

≜UCL

<ロト < 母 ト < 目 ト < 目 ト 、 目 ・ の Q ()

Theorem [HM11]

R(D, R, ;) is not finitely axiomatisable.

- Define ≤ implicitly by saying *a*; *D*(*b*); *c* ≤ *a*; *c* and close under transitivity
- 2. Define unrepresentable structures with *n*-length \leq -cycles, for each *n* < ω
- 3. Show that the non-principal ultraproduct of these unrepresentable structures is representable

Recall, for $S, T \subseteq X \times X$

$$S * T = \{(x, y) \in S; T \mid \forall z : (x, z) \in S \rightarrow (z, z) \in D(T)\}$$

This means that for all $S, T \subseteq X \times X$

$$D(S * T) * S = S * D(T)$$

Thus a * D(b) * c = D(a * b) * a * c and the \leq used to show R(D, R, ;) NFA can be finitely axiomatised in R(D, R, *).

・ロット 御マ キョマ キャ トロマン

<ロト < 母 ト < 目 ト < 目 ト 、 目 ・ の Q ()

Theorem

R(D, R, *) cannot be axiomatised by finitely many axioms.

- 1. Define \sqsubseteq implicitly, using more elaborate axioms
- 2. Define unrepresentable structures with *n*-length \sqsubseteq -cycles, for each $n < \omega$
- 3. Show that the non-principal ultraproduct of these unrepresentable structures is representable

Partial Converse and FRP

▲□▶▲□▶▲目▶▲目▶ 目 のへの

≜UCL

Definition

For every representable {D, R, ;}- and {D, R, *}-structure S, define a function $C : S \to \wp(S)$ such that for all $a, b \in S$ if $b \in C(a)$, it will be true that in every representation of S, the image of *b* will be above the converse of the image of *a*.

Why not use this to prove the FRP for converse-free Domain-Range signatures using the Ordered Domain Algebra argument?

Well, that proof relies on

However, it may be the case that

C(b); $C(a) \subsetneq C(a; b)$

Problems

Problems

Problem

Do converse-free Domain-Range Semigroups have the FRP? How about their demonic cousins?

Problem

What happens when + is added to the signature? Does the FRP still hold?

Conjecture

A signature $\tau \subseteq \mathit{RA}$ has the FRP if and only if

$$\{-,;\} \not\subseteq \tau \not\supseteq \{\cdot,;\}$$
