

A Variety Theorem for Relational Universal Algebra

RAMICS 2021

Chad Nester

(Tallinn University of Technology)

The Plan:

- Universal Algebra Refresher
- String Diagrams as Relational Syntax
- Relational Universal Algebra
- Variety Theorem & Morita Equivalence

Recall the theory of Commutative Monoids:

$$\Sigma = \{ m/\alpha, e/\circ \}$$

Subject to equations:

$$m(m(x,y),z) = m(x,m(y,z))$$

$$m(e(),x) = x$$

$$m(x,y) = m(y,x)$$

A model is a set X along with functions

$$m_x : X \times X \rightarrow X \quad e_x : 1 \rightarrow X$$

which satisfy the equations.

A model morphism $x \xrightarrow{f} y$ is a function satisfying:

$$f(m_x(x, y)) = m_y(f(x), f(y))$$

$$f(e_x(1)) = e_y(1)$$

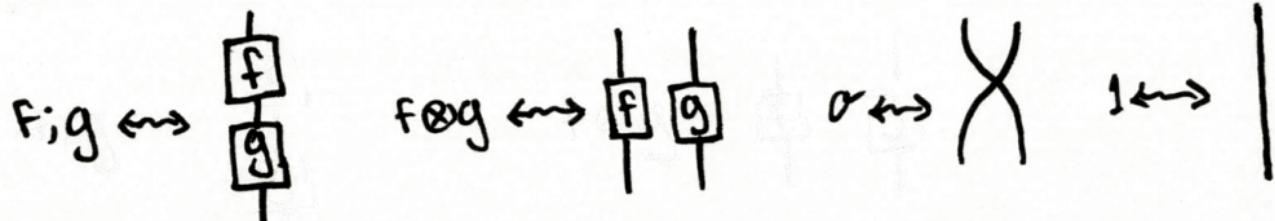

Resulting in the Category of monoids and monoid homomorphisms.

More Abstractly :

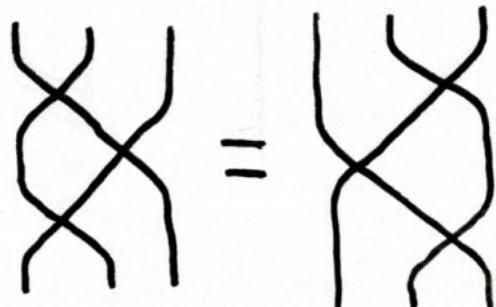

- Theories \leftrightarrow Categories \mathbb{X} w finite products
- Models \leftrightarrow Product-Preserving functors
 $\mathbb{X} \longrightarrow \underline{\text{Set}}$
- Model Morphisms \leftrightarrow Natural transformations

Categories that arise as the models and model morphisms of some theory are called Varieties.

String Diagrams / Symmetric monoidal Categories:

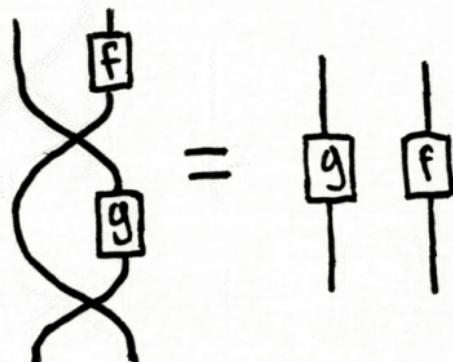

"Same" Diagram \leftrightarrow Same Arrow:

and

$$\begin{aligned}
 & (\alpha \otimes 1)(1 \otimes \alpha)(\alpha \otimes 1) \\
 & = (1 \otimes \alpha)(\alpha \otimes 1)(1 \otimes \alpha)
 \end{aligned}$$

$$(1 \otimes f)\alpha(1 \otimes g)\alpha = g \otimes f$$

Finite Products \leftrightarrow SMC w natural Comutative Comonoid structure:

$$\begin{array}{c} x \\ \diagup \quad \diagdown \\ x \quad x \end{array}, \quad \begin{array}{c} x \\ | \\ \bullet \end{array}$$

satisfying:

$$\begin{array}{c} f \\ \diagup \quad \diagdown \\ f \quad f \end{array} = \begin{array}{c} f \\ | \\ f \end{array} \quad \begin{array}{c} f \\ | \\ \bullet \end{array} = \bullet$$

(naturality)

$$\begin{array}{c} \diagup \quad \diagdown \\ \cap \end{array} = \begin{array}{c} \diagdown \quad \diagup \\ \cap \end{array}, \quad \begin{array}{c} \diagup \quad \diagdown \\ \times \end{array} = \begin{array}{c} \diagup \\ \cap \end{array}, \quad \begin{array}{c} \diagdown \\ \cap \end{array} = \mid$$

(Commutative Comonoid)

$$\begin{array}{c} x \otimes y \\ \diagup \quad \diagdown \\ x \otimes y \quad x \otimes y \end{array} = \begin{array}{c} x \quad y \\ \diagup \quad \diagdown \\ x \quad y \quad x \quad y \end{array}, \quad \begin{array}{c} x \otimes y \\ | \\ \bullet \end{array} = \begin{array}{c} x \\ | \\ \bullet \end{array}$$

(Coherence)

Theory of Commutative Monoids may be given as:

$$\begin{array}{c} x \\ \cup \\ o \\ x \end{array}, \quad \begin{array}{c} I \\ | \\ o \\ | \\ x \end{array} : \quad \begin{array}{c} \cup \\ o \\ \cup \\ o \end{array} = \begin{array}{c} \cup \\ o \end{array} \quad \begin{array}{c} \times \\ o \\ \times \\ o \end{array} = \begin{array}{c} \times \\ o \end{array} \quad \begin{array}{c} | \\ o \\ | \\ o \end{array} = \begin{array}{c} | \\ o \end{array} = 1$$

(monoidal signature)

(equations over free Cat. \cong finite products on the signature)

Notice that this includes the following equations implicitly:

$$\begin{array}{c} \cup \\ o \\ \cup \\ o \end{array} = \begin{array}{c} \cup \\ o \\ \cup \\ o \end{array} \quad \begin{array}{c} | \\ o \\ | \\ o \end{array} = \begin{array}{c} | \\ o \end{array} \quad \begin{array}{c} \times \\ o \\ \times \\ o \end{array} = \begin{array}{c} \times \\ o \end{array} \quad \begin{array}{c} | \\ o \\ | \\ o \end{array} = \begin{array}{c} | \\ o \end{array} = 1_I$$

The Associated Variety is again monoids & monoid homomorphisms

Now String diagrams Correspond to terms:

$$e \leftrightarrow \text{○}$$

$$x_1 \circ x_2 \leftrightarrow \text{U-shaped diagram}$$

$$(x_1 \circ x_2) \circ x_1 \leftrightarrow \text{Complex U-shaped diagram}$$

Composition is Substitution:

$$(x_1 \circ x_2) \circ x_1 \left[\begin{matrix} x_1 \mapsto e \\ x_2 \mapsto x_1 \circ x_2 \end{matrix} \right]$$

=

$$(e \circ (x_1 \circ x_2)) \circ e$$

$$\text{Diagram} = \text{Diagram}$$

Theorem: (Adámek, Lawvere, Rosický)

Two algebraic theories present the same variety iff splitting idempotents in each yields equivalent categories.

"Morita Equivalence"

(A consequence of their characterization of varieties)

What about theories whose operations are relations?

That is, models in Rel instead of Set.

- Classical Syntax \leftrightarrow Finite products •

Rel does not have finite products in the right way (\sqcup , not \times).

... So Classical term syntax won't really work!

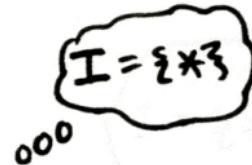

String diagram Syntax for relations:

$\{(a,(a,a)) \mid a \in X\}$

$\{(a,*), (*,a) \mid a \in X\}$

$\{((a,a),a) \mid a \in X\}$

$\{(*,a) \mid a \in X\}$

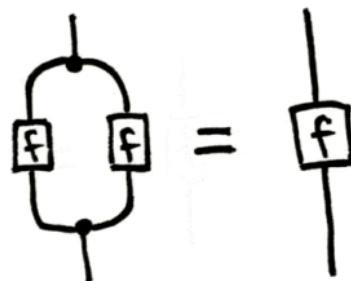

Forming a Commutative Special Frobenius Algebra:

$$\text{Diagram 1: } \text{Diagram 1a: } \text{Diagram 1b: } \text{Diagram 1c: }$$
$$\text{Diagram 1a} = \text{Diagram 1b} = \text{Diagram 1c} = |$$

$$\text{Diagram 2: } \text{Diagram 2a: } \text{Diagram 2b: } \text{Diagram 2c: }$$
$$\text{Diagram 2a} = \text{Diagram 2b} = \text{Diagram 2c} = |$$

$$\text{Diagram 3: } \text{Diagram 3a: } \text{Diagram 3b: } \text{Diagram 3c: }$$
$$\text{Diagram 3a} = | = \text{Diagram 3b} = \text{Diagram 3c} = |$$

Further, we ask that for all f :

which determines a meet & poset-enrichment:

$$f \sqcap g = \begin{array}{c} \text{AND gate} \\ \text{with inputs} \\ f \quad g \end{array}$$

$$f \sqsubseteq g \Leftrightarrow f \sqcap g = f$$

g includes f

A Relational Algebra Theory is a symmetric monoidal Category with this structure.

A model is a structure-preserving functor

$$\mathbb{X} \xrightarrow{F} \underline{\text{Rel}}$$

Aside:

Categories with this structure were introduced by Carboni & Walters in 1987, under the name "Cartesian bicategories of Relations".

A model morphism $\alpha: F \rightarrow G$ is a lax transformation.

That is, a family of arrows $\alpha_x: FX \rightarrow GX$

satisfying:

$$\begin{array}{ccc} x & & \\ \downarrow f & \Rightarrow & \downarrow Ff \\ Y & & \end{array} \quad \begin{array}{ccc} FX & \xrightarrow{\alpha_x} & GX \\ \downarrow & \subseteq & \downarrow Gf \\ FY & \xrightarrow{\alpha_y} & GY \end{array}$$

where \subseteq is the inclusion ordering:

$$f \subseteq g \Leftrightarrow f \circ g = f \quad (\text{introduced earlier})$$

For example the theory of nonempty sets is the free such category on one generating object and no generating arrows subject to:

$$I = \boxed{\quad} = 1_I$$

Models are nonempty sets:

$$\begin{aligned} I &= \{(*, a) \mid a \in X\}; \{a, *\} \mid a \in X\} \\ &= \{(*, *) \mid \exists a \in X\} \end{aligned}$$

Model Morphisms are functions.

The theory of regular semigroups is generated by:

$$\text{U} : \text{U} = \text{U} \times \text{U}$$

$$\text{U} = \text{U}$$

$\forall a \in E \exists b \in E. aba = a$ - "Regularity"

Models are regular semigroups.

Model morphisms are semigroup homomorphisms.

Categories are captured by the 2-sorted theory:

$$\begin{array}{ccccc} A & A & O & A & A \\ \vdash & \vdash & \circ & \cup & \cap \\ \vdash & \vdash & O & A & A \end{array} : \quad \vdash = \text{!} \quad \vdash = \text{!} \quad \circ = \text{!}$$

$$\vdash = \vdash \quad \circ = \circ \quad \vdash = \vdash \quad \vdash = \vdash$$

$$\vdash = | \quad \vdash = | \quad \circ = \circ \quad \vdash = \vdash$$

$$\vdash = | \quad \vdash = | \quad \vdash = \vdash \quad \vdash = \vdash$$

Models are (small) categories.

Model morphisms are functors. Here it is important that we use lax transformations:

$$\begin{array}{c} A \\ \downarrow F \\ B \end{array} : \begin{array}{c} \text{---} \\ \downarrow F \\ \text{---} \end{array} = \begin{array}{c} F \\ \downarrow \\ \text{---} \end{array} \quad \begin{array}{c} \text{---} \\ \downarrow F \\ \text{---} \end{array} = \begin{array}{c} F \\ \downarrow \\ F \end{array} \quad \begin{array}{c} F \\ \downarrow \\ \circ \end{array} = \begin{array}{c} \circ \\ \downarrow \\ F \end{array}$$

$$\begin{array}{c} \circ \\ \downarrow F \\ F \end{array} \Leftarrow \begin{array}{c} \text{---} \\ \downarrow F \\ \text{---} \end{array} \quad \begin{array}{c} \text{---} \\ \downarrow F \\ \text{---} \end{array} \quad \begin{array}{c} \text{---} \\ \downarrow F \\ \text{---} \end{array}$$

if f, g are composable then
so are Ff, Fg and $F(fg) = FfFg$.

Variety Theorem

Theorem:

The Categories that arise as the models and model morphisms of some relational algebraic theory are precisely the "definable categories".

"definable categories" ↗

Kuber & Rosický 2016

Lack & Tendas 2019

Morita-Equivalence

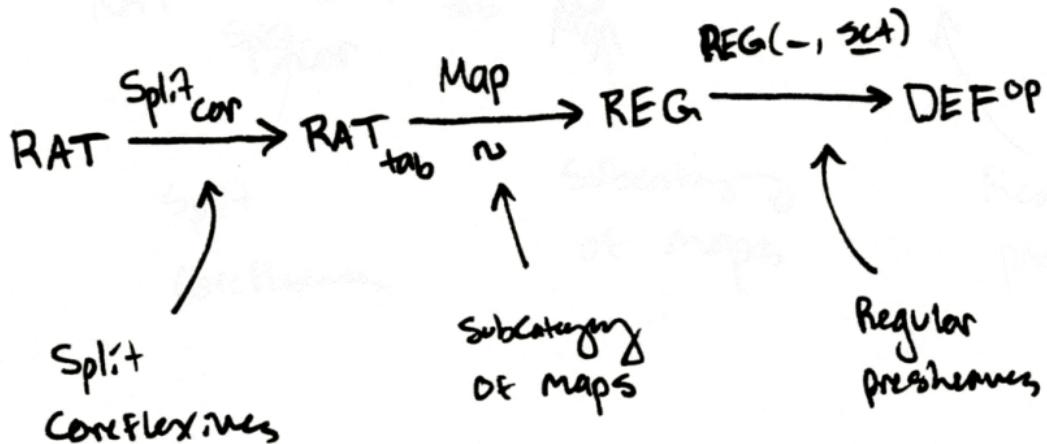

Theorem:

TWO relational algebraic theories present the same definable category IF and only IF splitting partial equivalence relations yields equivalent categories.

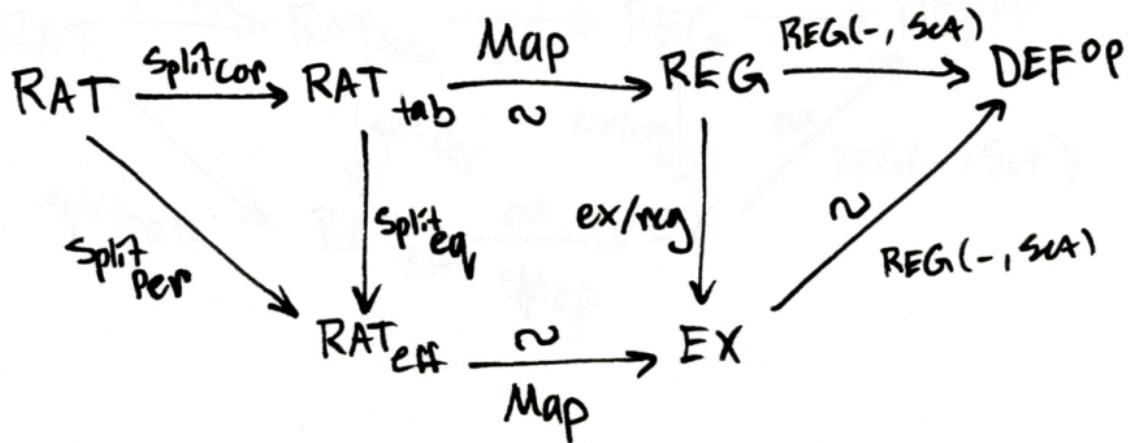

Possibly just splitting idempotents
(Categories, Allegories 2.16(11))
